

YouTube SQLite → ODBC Connection Guide

Short technical setup guide for the YouTube Analytics database

1. Architecture

YouTube Data → SQLite Database → SQLite ODBC Driver → Application / Reporting Tool

The project uses **youtube_data.db** as the SQLite database. The ODBC layer provides a standard connection interface between the SQLite database and compatible applications.

2. SQLite Database

Keep the database in a stable project location, for example:

```
PROJECT_ROOT/data/youtube_data.db
```

Before publishing, verify that the expected tables (such as **channels** and **videos**) are present and contain data.

3. Configure SQLite ODBC

1	Install a 64-bit SQLite ODBC driver.
2	Open Windows → ODBC Data Sources (64-bit).
3	Go to System DSN → Add.
4	Select the installed SQLite ODBC driver.
5	Create a DSN named YouTube_SQLite.
6	Select the full path to youtube_data.db.
7	Use Test Connection and confirm success.

4. Test the Connection

After creating the DSN, verify that the database can be queried:

```
SELECT * FROM channels LIMIT 5;
SELECT * FROM videos LIMIT 5;
SELECT COUNT(*) FROM videos;
```

If these queries return data, the ODBC connection is successfully reaching the SQLite database.

5. Development vs Production

For a cleaner setup, use separate databases/DSNs when testing changes:

```
YouTube_SQLite_DEV → youtube_data_dev.db
YouTube_SQLite_PROD → youtube_data.db
```

Important: ODBC is a connection layer. It does not automatically convert SQLite into SQL Server or another database. Moving the database to a cloud or server platform requires a separate migration/deployment process.
